NEW DELHI - Excessive irrigation and the unrelenting thirst of 114 million people are causing groundwater levels in northern India to drop dramatically, a problem that could lead to severe water shortages, according to a study released Wednesday.

Levels have dropped as much as a foot a year between 2002 and 2008, for a total of 26 cubic miles of water that vanished — enough to fill Lake Mead, the largest manmade reservoir in the United States, three times.

The study comes as India's struggles with water have become a major political issue. The problem reaches across the country's vast class divide, touching everyone from residents of elite neighborhoods where the taps regularly go dry to poor farmers in desperate need of irrigation to grow their crops.

Giving free electricity to farmers — who use that electricity to pump more groundwater — has become a common promise by campaigning politicians. That, though, simply makes the problem worse.

"This issue is of grave importance," said K. Sreelakshmi, a natural resource economist at New Delhi's Energy and Resources Institute, TERI. Sreelakshmi, who was not connected to the study, noted that previous research projects had revealed lowering groundwater, though this one used a new approach by relying on satellite data.

"The question is what do we do about the problem," she said. "How do we recharge" India's dropping water table?

### **NASA-led study**

The study, led by Matthew Rodell of the United States' [NASA](#) Goddard Space Flight Center in Maryland, indicated that groundwater across a swath of India from New Delhi into heavily farmed agricultural belts dropped at an average rate of 1.6 inches per year between August 2002 and October 2008. That decrease in groundwater is more than double the capacity of India's largest reservoir.

"The region has become dependent on irrigation to maximize agricultural productivity," Rodell said in a statement. "If measures are not taken to ensure sustainable groundwater usage, the consequences for the 114 million residents of the region may include a collapse of agricultural output and severe shortages of potable water."

The study noted that the drop in groundwater came in years where there was no shortage of rainfall to cause a natural decline.

Some water wells in northern India, like this one surrounded by bricks near a construction site in Gahroh, have been abandoned after drying out.

The region, though, has seen an enormous increase in water use since the 1960s. Part of that is because of the growing population, though even more resulted from the so-called Green Revolution, which dramatically increased India's agricultural production — in part by exponentially expanding the use of groundwater for irrigation.

"Severe groundwater depletion is occurring as a result of human consumption," the researchers concluded in the study, released online

in the journal Nature.

The study was based largely on data provided by GRACE — the Gravity Recovery and Climate Experiment — a satellite system launched in 2002 by NASA and the German Aerospace Center. GRACE allows scientists to estimate changes in groundwater storage by measuring tiny variations in the Earth's gravitational pull.

**Pakistan, Bangladesh cited earlier**

Another [recent study](#) based on GRACE data, using results from a 1,200-mile swath across eastern Pakistan, northern India and into Bangladesh, showed about 1.9 million cubic feet of groundwater lost per year.

That study, in *Geophysical Research Letters*, was led by geophysicists Virendra Tiwari of the National Geophysical Research Institute in Hyderabad, India; John Wahr of the University of Colorado, Boulder; and Sean Swenson of the National Center for Atmospheric Research in Boulder.

"This is probably the largest rate of groundwater loss in any comparable-sized region on Earth," that study said.
